Abstract

This journal presents the design and development of Lifeguard X, a cutting-edge remote controlled lifeguard technology designed to revolutionize water rescue operations by providing quick, reliable, and self-sustained responses to aquatic emergencies. The technology is proposed to improve on the limitations of conventional lifeguard systems, including slow response time, exposure of human rescuers to danger, and difficulties presented by turbulent water conditions. Lifeguard X employs state-of-the-art technology to combine several key elements, such as accurate navigation, obstacle sensing, and flotation assistance. These elements function in a coordinated manner to provide an efficient and automated response to drowning situations. The GPS navigation enables Lifeguard X to find and approach people in distress with high accuracy, with little delay in life-threatening situations. Obstruction detection using ultrasonic sensors increases safety as the device can independently travel through congested or debris-filled waters, thus evading dangers. The flotation support system provides an added layer of security by automatically providing buoyancy to people in distress and supporting them in staying afloat until help can reach them. This combination of features within Lifeguard X presents a complete solution that values the safety of lifeguards and victims alike. With autonomous and remote-controllable features, it is exceedingly versatile for implementation in different body of water ecosystems, including shores, lakes, pools, and offshore platforms. With these technology advancements, Lifeguard X represents a new benchmark in water rescue technology, permitting quicker, more secure, and more effective rescues, thus helping to significantly reduce drowning related incidents globally.

Keywords: Water Rescue Operation, Accurate Navigation, Safety, Security.

DOI: <https://doi.org/10.5281/zenodo.15099348>

1. Introduction

Drowning is a serious and ongoing global health problem, with the World Health Organization (WHO) declaring it as the third most common cause of unintentional injury-related death globally, with more than 236,000 deaths occurring each year. Children and young people, as well as those from low-resource settings, are most at risk, with most drowning happening in bodies of water like oceans, lakes, rivers, and swimming pools. The urgency of drowning accidents are highlighted by the life-risking consequences of delayed action in water rescue situations.

Distances from the shore, state of the water, and human lifeguard limitation are among the reasons for these delays, occasionally with lethal consequences. Therefore, there is an increased demand for quicker and safer rescue systems. To overcome the limitations of conventional water rescue techniques, the current project suggests Lifeguard X: a remote-operated, high-speed water rescue system aiming to help lifeguards rescue drowning victims promptly and securely. Lifeguard X features several innovative features, including:

Accurate Navigation: Employing GPS and sensor-guided navigation, the system is able to reach the position of the drowning victim precisely, irrespective of environmental hurdles.

Real-Time Monitoring: With high-definition cameras, Lifeguard X gives the operator live visual feedback, ensuring precise control and proper evaluation of the rescue scenario.

Flotation Support: The device inflates an inflatable flotation aid once it reaches the victim, enabling them to stay afloat until further help comes.

Obstacle Detection and Autonomous Navigation: Ultrasonic detectors and control software allow the device to detect obstacles and reach safely in differing water conditions. This unit can be used remotely by a lifeguard or rescue crew or operated autonomously to be able to swim to the drowning victim when there is restricted or no operator control. The combination of modes makes Lifeguard X useful both in controlled atmospheres, such as swimming pools, and the more variable natural environments, including oceans and lakes.

2. Literature Review

In recent times natural disasters like hurricanes, floods or droughts have been on the rise due to climate change everywhere in the world. For instance, Hurricane Katrina hit the Gulf Coast of USA in August 2005 and inflicted severely damaging effects from central Florida to eastern Texas. Similarly, Chennai in India was inundated by heavy rains of the annual northeast monsoon during November-December 2015, therefore we design a remote-controlled rescue robot with ZigBee communication. Caterpillar is used as the rescue robot's body with two crawlers of arm. Two arm crawlers are employed in crawling over an obstacle. Two arm crawlers are controlled through the Arduino UNO microcontroller. In addition, a Wi-Fi camera is mounted on the caterpillar, and the user can look at the circumstances of a disaster zone by Wi-Fi camera using PC.[1].

The difficult aspect is that the rescuers and the victims must both be safe; the first and main priority is to save lives. During this era of new technologies and automation, robots can be of a great advantage to achieve this goal either by directly or indirectly engaging with victims or by aiding protection gear. The primary responsibility of the rescue team's mission to find the human survivors on the accident site, and it is a dangerous mission that usually results in the loss of lives.[4].

Successful rescues depend on data, voice and video communication between the control station and the robot. The data communication must be used to transmit orders to the robot and to deliver essential information of the

environment. Video feeds from the robot enable rescuers to see hazardous conditions, while voice communication permits the rescuers to speak to victims for information and also to console them. [6]

The U-shaped buoy that is remote-controlled is a fast and efficient method of saving lives. It is an ingenious lifesaving design consideration to make this lifebuoy U-shaped in such a way that a person who is drowning or hurt and cannot swim can understand and receive support from the U-shaped buoy. Through a remote control, a U-shaped lifesaver buoy is able to travel itself across the water and, if needed, rescue a victim to shore. [9]

3. Block Diagram

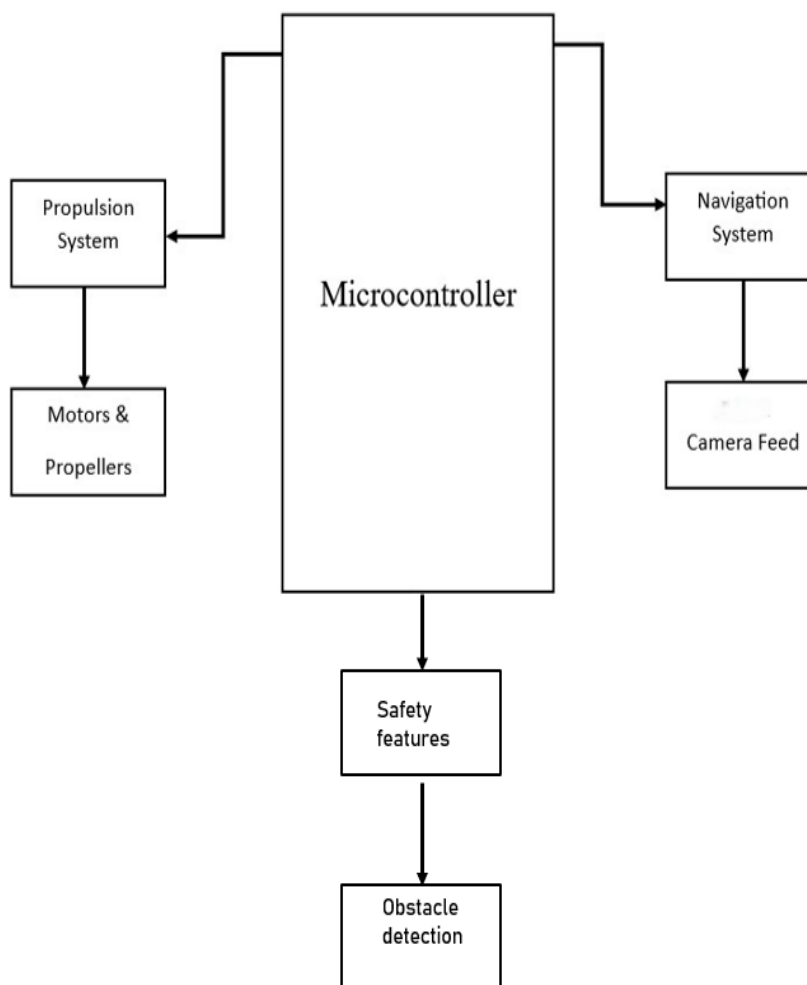

Figure1: Block Diagram

The block diagram depicts the Lifeguard X system architecture, which is optimized for effective water rescue. The microcontroller is at the center of the system, coordinating all the elements. It receives data from the navigation system, GPS module, camera input, and safety features and processes them to enable effective operation. The navigation system has GPS for real-time location and a camera input for live video monitoring, which allows proper path planning and manual control where required. The system for propulsion, which is driven by motors and

propellers, provides a smooth ride in water, and the motor driver regulates speed and direction. The system's reliability is boosted by safety features such as automatic return-to-home mode in the event of signal loss, real-time obstacle detection using ultrasonic sensors, and a servo motor that deploys an inflatable life jacket to ensure immediate flotation support to drowning patients. The whole system works harmoniously, providing accurate navigation, avoiding obstacles, and quick response, making it a strong solution for water rescue operations.

4. Circuit Diagram

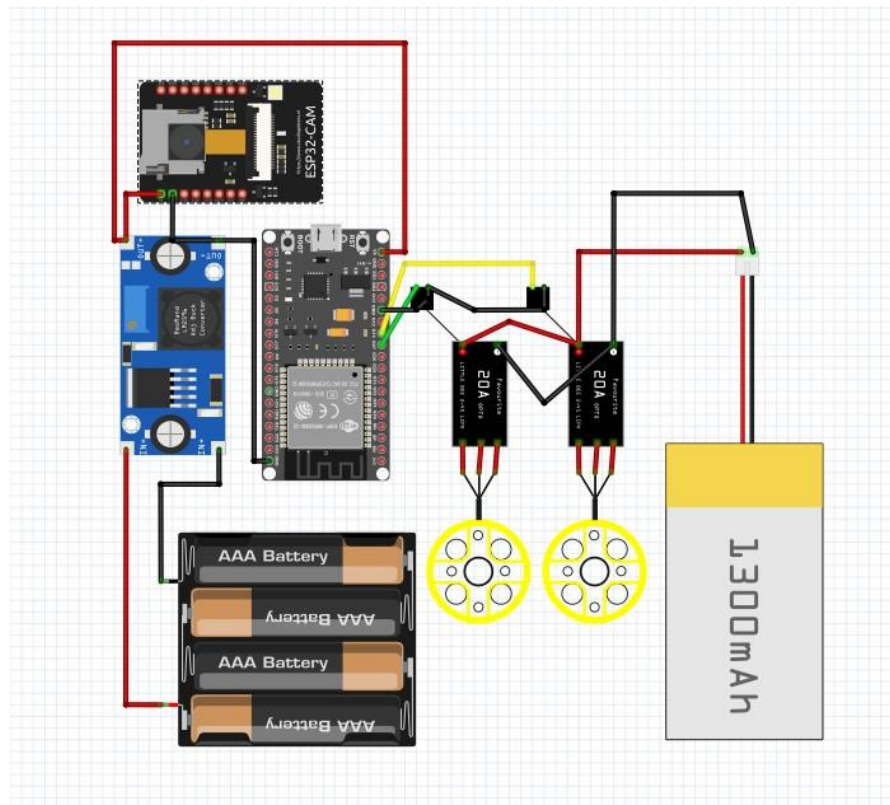

Figure 2: Circuit Diagram

An important part of Lifeguard X is the ESP32-CAM, which is responsible for showing a live feed to the operator. This is possible through real-time video monitoring, thereby making navigation accurate and situational awareness possible. Rescuers can remotely diagnose the state of the victim using this function and adjust as required the movements of the device to ensure smooth rescue operations.

Propulsion system is based on a Brushless DC (BLDC) motor, which yields powerful thrust in propelling the device in the water. The motor creates smooth movement in a number of directions like forward, backward, and turning, enabling the device to go to the site of the drowning victim at speed. To handle the speed and direction of the motor, an Electronic Speed Controller (ESC 30A) is used. The ESC is regulated by control received from the ESP32 and adjusts the power of the motor accordingly to facilitate stable and efficient movement. When activated, Lifeguard X swims towards the drowning individual under the operator's control through the live video feed. The propulsion and

steering can only be achieved while the device is in operation to prevent unintended movement when stationary. In times of emergency, the device can quickly change direction, making it a secure and trustworthy solution for rescue missions.

With the integration of advanced motor control, wireless data transmission, and live video streaming, Lifeguard X provides an affordable, secure, and autonomous rescue solution for water rescues. It reduces response time dramatically and reduces risks to human rescuers, making it an invaluable tool for lifesaving interventions in hazardous aquatic environments.

5. Challenges and Limitations

Environmental Challenges: Water rescue missions usually take place under adverse weather conditions, for example, rough currents, rough waves, or inclement weather, which are likely to affect the performance of GPS navigation, obstacle detection, and propulsion systems. Maintaining consistent performance under unsteady surroundings continues to pose a major challenge.

Hardware Durability: Chronic exposure to water, particularly seawater, might lead to corrosion and destruction of electronic parts and motors. A fully waterproof and resilient system, designed to hold up against such exposure while keeping it functional is paramount.

Obstacle Avoidance: Obstacle detection and path planning around them in dynamic underwater environments, e.g., floating debris, boats, or swimmers, is challenging. Fine-tuning ultrasonic sensors and algorithms for real-time and reliable obstacle detection is paramount.

Power Management: Power is needed to drive the propulsion system, sensors, camera, and microcontroller. Optimizing battery life, weight, and efficiency for long operating time without sacrificing performance is a serious challenge.

Communication and Connectivity: It may be challenging to have a stable Wi-Fi connection between the operator and Lifeguard X in long range rescues or in remote locations. Solutions like increased signal range or other means of communication like LoRa may be necessary for reliability.

Deployment and Retrieval: The device should be designed for easy deployment and retrieval, either from shore or a moving boat, without incurring delays or system damage, necessitates careful design consideration of the device and weight distribution.

Cost and Scalability: Making Lifeguard X affordable for mass production and available for use on a broad scale is another challenge. Striking a balance between high-technology and cost is essential to facilitate adoption among commercial and non-profit rescue entities. Overcoming these challenges includes iterative testing, component refinement, and incorporating cutting-edge technologies to enhance Lifeguard X's reliability, efficiency, and usability in actual situations.

6. Scope

As technology advances a number of improvements and additions could further enhance the functionality and sustainability of Lifeguard X. These future developments target growing the effectiveness, efficiency, and flexibility of the device across a broad scope of water rescue uses, keeping it on the leading edge of water safety technology. Future releases may involve the following:

AI-Based Drowning Detection Algorithms: The use of Artificial Intelligence (AI) can greatly enhance Lifeguard X's ability by providing autonomous detection of drowning persons. AI-powered algorithms, employing machine learning and computer vision, may be trained to identify distress signals, abnormal movement patterns, or particular body positions that signify drowning. This technology would enable Lifeguard X to detect a person in distress automatically and trigger rescue efforts without human involvement. This feature would be particularly useful in big, populated aquatic environments where manual checking can be hard, thus lowering response times and potentially saving lives.

Solar-Powered Charging Systems: To tackle the issue of battery life in extended or far-off rescue efforts, Lifeguard X may be fitted with solar-powered charging systems. Solar panels built into the device design would enable it to keep recharging under sunlight, thereby increasing its functional time in remote or extended missions. This upgrade would not only enhance efficiency but also render the device more sustainable by decreasing dependence on traditional charging infrastructure. Solar-powered charging is also especially beneficial for deployment in sunny, high-exposure settings, like beaches and coastal regions.

Advanced Battery Technology: Along with solar power, advances in battery technology, like the use of lithium-sulphur or solid-state batteries, could further increase the energy storage capacity and longevity of Lifeguard X. These advanced batteries provide increased energy density, quicker charging time, and longer lifespan than standard lithium-ion batteries. Enhanced battery performance would enable the device to support more prolonged and demanding operations, enabling it to be even better suited for large-scale use and emergency situations.

Modular Design to Customize: Future versions of Lifeguard X may incorporate a modular design style, so users can customize the device according to certain requirements or situations. Such a design would support simple going upgrades, i.e., installing specialized sensors, new cameras, or mounting extra flotation equipment. Such modularity would increase the device's flexibility, making the device appropriate for various applications, ranging from coastal rescue and lake patrol to factory safety and disaster relief.

Night Vision and Thermal Imaging Capability: Installation of night vision or thermal imaging cameras might improve the device's effectiveness in low-light or nighttime rescue scenarios. Thermal imaging, in particular, could detect body heat, allowing Lifeguard X to locate victims even in poor visibility conditions, such as during nighttime or in murky water. This capability would expand the operational scope of the device, enabling it to function reliably around the clock, thus providing an all-weather, all-time rescue solution.

Improved Communication and Cooperation with Rescue Drones: Future improvements can include smooth integration and cooperation with rescue drones to create an extensive rescue system where both aerial and aquatic capabilities work in unison. While Lifeguard X covers the victim on water, cameras or other flotation devices on drones may offer a zone.

Improved Real-Time Data Analytics: Improved future iterations of Lifeguard X may include improved data analytics systems to give environmental evaluations in real time. With added sensors, like water quality monitors, temperature detectors, and current meters the gadget could inspect conditions that would affect the safety of swimmers or influence the rescue process. Real-time information on wave height, currents, and visibility could be transmitted back to the rescue teams, providing critical inputs for making situational, well-informed decisions. This aspect would be crucial extremely useful to lifeguards and emergency services personnel working within complicated or risky aquatic settings.

7. Result

Figure 3: Result

8. Conclusion

The future potential for Lifeguard X is vast, with many avenues for technological advancement and functional extension. The incorporation of AI-driven detection, renewable power sources, IoT connectivity, modular customization, and sophisticated data analytics could turn Lifeguard X into a highly advanced and adaptable tool for water safety. These advancements will allow Lifeguard X to address the changing needs of water rescue operations, making it an invaluable tool for lifeguard squads, coastal guards, and emergency responders. Through ongoing research and development, Lifeguard X can establish a new benchmark in aquatic rescue technology, ultimately leading to safer, more efficient water environments on the planet.
